Hypothesis: items in working memory are attracted by nearby distractors and this will bias a subsequent perceptual report

Clockwise trials: the target is CW from the distractor

E

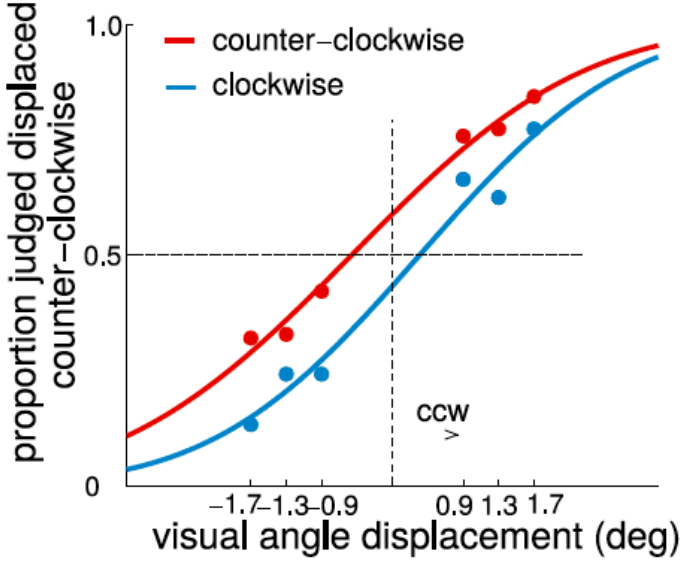

stimulus

1. During the delay, the remembered target is increasingly attracted to the distractor (CCW)

2. When presenting the probe, it appears to be displaced more clockwise than it actually is (in the cartoon, the probe is shown at the previous target location, i.e. zero displacement, and it should be perceived displaced clockwise)

F

Panel F shows that, in clockwise trials, the displacements are judged more clockwise than they actually are

Counter-clockwise trials: vice versa
